Abstract
In this article, analytical and numerical methods were employed to study swelling behavior of a cylindrical shell made of a functionally graded temperature sensitive hydrogel. The hydrogel shell has gradient property in radial direction. The shell cross-linking density is a linear function of the radial coordinate of the FGM shell. The analytical model was first developed for the hydrogel shell and a second order differential equation was derived which can be solved by numerical methods. Then, finite element solution of the under-study functionally graded hydrogel shell was performed by implementing the material model in ABAQUS software and by writing a user-defined subroutine. In this regard, the functionally graded hydrogel shell was modeled as multi-layered shell with discrete material properties. A good agreement between the analytical results and numerical simulation was observed and validity of analytical solution was confirmed. Thereafter, analytical model was employed to study the swelling behavior of functionally graded shell for different thickness ratios of the shell.

Nomenclature

| F  | Deformation gradient tensor |
| J  | Determinant of deformation gradient tensor |
| $W_{\text{elastic}}$ | Elastic free energy density of the network |
| N  | Cross-linking density of the hydrogel network |
| $\lambda_0$ | Equilibrium stretch |
| $\nu$ | Volume of a water molecule |
| K  | Boltzmann constant |
| $I_1$ | First invariant of $C$ |
| C  | Right Cauchy-green deformation tensor |
| $\lambda_0, \lambda_1$ | Interaction parameters with material constants |
| $W_{\text{mixing}}$ | Mixing free energy density of the network |
| $N_0, N_1$ | Cross-linking density values in the inner and the outer radii of the shell |
| $\alpha$ | Governing equation constant |
| $P_r$ | Radial stress |
| $P_t$ | Tangential stress |
| $A, B$ | Inner and outer radiuses |

1. Introduction

Smart hydrogels can absorb water due to environmentally stimuli such as pH [1, 2], temperature [3, 4], light [5, 6] etc. Thus, utilizing these materials as smart sensors and actuators has been interesting for researchers, especially with applications in microfluidics such as micro-valves and micro-pumps [7-9]. For precise study and design of these devices, use of constitutive equa...
tion of the hydrogel is necessary in simulations. Thus, numerous works were conducted to obtain appropriate constitutive model for these materials. Hong et al. [10] studied the coupled diffusion and large deformations of a neutral hydrogels which is the base of the other works in recent years. Chester and Anand [11] presented a constitutive model for temperature sensitive hydrogels and developed a numerical tool for implementation of their model in ABAQUS. Furthermore, Chester et al. presented a numerical tool for coupled diffusion and large deformations of the gels which were imported in ABAQUS [12]. Cai and Suo [13] presented a constitutive model for the temperature sensitive PNIPAM hydrogels with a good ability in prediction of the experimental data. Thereafter, Mazaheri et al. [14] developed a stable model for PNIPAM hydrogels along with Cai and Suo model. Moreover, Mazaheri [15] presented a constitutive model which considers the inextensibility of the hydrogel chains due to large deformations occurring in swelling.

As mentioned above, one of the main applications of the smart hydrogels is in sensors and actuators. Thus, some researchers studied the behavior of these devices exposed to environmental stimuli. Beeb et al. [7] proposed a novel hydrogel micro-valve for using in microfluidics which has attracted great deal of interest of researchers. Additionally, Kim and Beebe [16] presented a bi-polymer hydrogel micro-valve for use as a one-way micro-valve. He et al. [17] studied a pH-sensitive hydrogel micro-valve numerically. Mazaheri et al. [18] conducted analytical and numerical studies on a micro-valve made of temperature sensitive hydrogel. Arbabi et al. [19] studied the behavior of a pH-sensitive micro-valve by considering fluid-solid interaction (FSI) between hydrogel part of the micro-valve and the rigid walls of the micro-valve. Mazaheri et al. [20] performed an FSI study on a one-way smart hydrogel micro-valve in which the FSI effect was important.

In this work, swelling of a cylindrical hydrogel shell is studied by using analytical and numerical methods in which the shell property was assumed to be functionally graded along radial direction. The density of cross-linking of the shell was a linear function of the radial coordinate in the reference state of the shell. The assumed cylindrical hydrogel shell was the main part of the hydrogel micro-valves for which the temperature dependent swelling was investigated. The analytical results for the FGM cylindrical shell were compared with the numerical results to confirm its validity. Then, the analytical model was employed in parametric study of the FGM hydrogel shell.

This work is presented in different sections. First, a brief review on the constitutive equation of the temperature sensitive hydrogels is provided in section 2. Then, the analytical approach is developed in section 3 for the cylindrical hydrogel shell. The finite element method for the problem is discussed in section 4. The obtained results are demonstrated in section 5 in which a parametric study is also performed. Finally, conclusions of this work is briefly mentioned in section 6.

2. Temperature Sensitive Hydrogel Modeling

Denoting the coordinate of a particle in reference and current states by $X$ and $X(X)$, and introducing the deformation gradient tensor $F = \frac{\partial X}{\partial X}$, the right Cauchy–Green deformation tensor is [14]:

$$C = F^TF$$  \hspace{1cm} (1)

where $F^T$ is transpose of $F$. Considering the incompressibility of the hydrogel chains and water molecules, and employing an additive decomposition of the free energy density, the free energy density for hydrogels has elastic and mixing sources as [10]:

$$W = W_{\text{elastic}} + W_{\text{mixing}}$$  \hspace{1cm} (2)

where $W_{\text{elastic}}$ and $W_{\text{mixing}}$ are elastic and mixing free energy density of the network due to mechanical deformations and mixing hydrogel chains with water molecules and are as follows [14]:

$$W_{\text{elastic}} = \frac{1}{2} NKT(I_1 - 3 - 2 \log(J))$$

$$W_{\text{mixing}} = \frac{KT}{\nu}(J - 1) \times \left( - \frac{1}{J} - \frac{1}{2J^2} - \frac{1}{3J^3} + \frac{X_0}{J} + \frac{X_1}{J^2} \right)$$

in which $J = \det(F)$ and $I_1$ is first invariant of $C$. Furthermore, $\nu$, $K$, and $N$ are volume of a water molecule, Boltzmann constant, and cross-linking density of the hydrogel network, respectively. $T$ is absolute temperature and, $X_0 = A_0 + B_0 T$ and $X_1 = A_1 + B_1 T$ are the interaction parameters with material constants of PNIPAM hydrogel presented by Afroze et al. [21] as presented in Table 1.

Now, nominal stress components can be calculated by differentiating $W$ with respect to $F$ as will be discussed in the next section. For implementing the constitutive equations in ABAQUS, the free energy function was rewritten with respect to a reference state with equilibrium stretch of $\lambda_0$. Thus, the free energy, was normalized by $\lambda_0^3$ and also, $J$ and $I_1$ were multiplied by $\lambda_0^3$ and $\lambda_0^5$, respectively [22]. It should be noted
that the equilibrium stretch of $\lambda_0$ at a specified temperature was calculated by setting the obtained stress components to zero (free swelling state) and solving the equation for $\lambda_0$ [14].

### 3. Analytical Solution

In this work, it is assumed that the micro-valve has a cylindrical hydrogel sensitive layer rested on a rigid core as depicted in Figure 1 for both FGM and layered design in the reference state. The layered shell was used in FEM simulations as explained in the following. The initial or reference state of the micro-valve was considered at 310K (reference temperature) with a free-stress state. $A$ is the inner radius and $B$ is the outer radius of the shell for both FGM and layered shells. The layered shell was studied numerically to verify the FGM analytical solution.

![Fig. 1](image)

**Fig. 1.** Schematic of the under-study micro-valve in the reference state for both a) FGM and, b) Layered shells.

As the temperature decreases from the reference temperature, the hydrogel layer experiences more swelling and as a result, radial and tangential components of stress are developed in the hydrogel layer. Denoting the radial and tangential nominal stress components with $P_r$ and $P_{\theta}$, and considering cylindrical symmetry, the equilibrium equation and related stretch components for plain strain condition are calculated as [18]:

\[
\frac{dP_r}{dR} - \frac{(P_r - P_{\theta})}{R} = 0, \quad \lambda_r = \frac{r}{R}, \quad \lambda_\theta = \frac{d}{dr} r(R)
\]

where $R$ and $r(R)$ are the radial coordinate of a particle in the reference and current states, respectively. In addition, $\lambda_r$ and $\lambda_\theta$ are radial and tangential stretches, respectively. The hydrogel layer is a functionally graded material in radial direction in which the cross-linking density of the shell, $N$, varies linearly with respect to radial direction as below:

\[
N = N_0 + \left( \frac{R - A}{B - A} \right) (N_1 - N_0)
\]

where $N_0$ and $N_1$ are cross-linking density values in the inner and the outer radii of the shell, respectively. The normalized stress components are calculated by differentiating $W$ with respect to radial and tangential stretches, $\lambda_r$ and $\lambda_\theta$, as below:

\[
\frac{P_r}{kT} = N_\nu \left( \frac{\lambda_r}{\lambda_0} - \frac{1}{\lambda_0^3 \lambda_r^3} \right) + \left( \frac{-1}{2} + (\lambda_0 - \lambda_1) \right) + \frac{1}{3} + 2 \lambda_1 - \frac{1}{\lambda_0^3 \lambda_r^3}
\]

\[
\frac{P_{\theta}}{kT} = N_\nu \left( \frac{\lambda_\theta}{\lambda_0} - \frac{1}{\lambda_0^3 \lambda_\theta^3} \right) + \left( \frac{-1}{2} + (\lambda_0 - \lambda_1) \right) + \frac{1}{3} + 2 \lambda_1 - \frac{1}{\lambda_0^3 \lambda_\theta^3}
\]

(6)

Substituting the nominal stress components in the equilibrium equation and considering the stretch definition, a second-order differential equation is obtained for swelling behavior of the micro-valve which besides the boundary conditions forms a boundary value problem. The obtained differential equation is:

\[
(\alpha_1 + \alpha_2 + R^2) R^2 r'' + \alpha_3 R^4 r^6 + \alpha_4 R^4 r^5 + \alpha_5 R^2 r'^4 + \alpha_6 R^2 r'^3 + \alpha_7 R^4 r'^2 + R^2 r' = 0,
\]

(7)

where:

\[
\alpha_1 = \frac{N \nu \lambda_0^3}{4} (\frac{\lambda_0^3 r'^2}{2} + 1),
\]

\[
\alpha_2 = \frac{\lambda_0^3 r'}{2} \left( \lambda_0^3 (\lambda_0 - \lambda_1) - \frac{1}{2} \right) + 3 \left( \frac{\lambda_1 - \frac{1}{6}}{r} \right),
\]

\[
\alpha_3 = \frac{\lambda_0^3 (R(N \nu)' + N \nu)},
\]

\[
\alpha_4 = \frac{N \nu \lambda_0^3}{4} (2 r^2 - \lambda_0^3 r'^2),
\]

\[
\alpha_5 = -\frac{\lambda_0^3}{4} \left( \left( \lambda_0 - \lambda_1 \right) R^2 + \lambda_0^3 r^2 (R(N \nu)' + N \nu) \right),
\]

\[
\alpha_6 = -\frac{\lambda_0^3}{4} \left( 3 \left( \frac{\lambda_1 - \frac{1}{6}}{r} \right) R^2 - \lambda_0^3 r^2 \left( \lambda_0 - \lambda_1 - \frac{1}{2} \right) \right),
\]

\[
\alpha_7 = \frac{3 \left( \frac{\lambda_1 - \frac{1}{6}}{r} \right) \lambda_0^3 r'^2}{2} + r^2.
\]

The hydrogel layer experiences zero displacement and zero stress in the inner and the outer radii of the shell as:

\[
r = A \quad \text{at} \quad R = A, \quad P_r = 0 \quad \text{at} \quad R = B.
\]

(9)

where $A$ and $B$ are introduced in Fig. 1. The solution of the above boundary value problem should be
obtained by using Richardson extrapolation in a finite difference scheme [23]. This scheme is available in commercial software of Maple. In the next section, the analytical results are presented beside the numerical results to validate the analytical approach.

4. Numerical Simulation

In this section, the FGM micro-valve is studied numerically by considering the hydrogel as a multi-layered cylindrical shell with discrete properties to validate the analytical results. To this end, the constitutive model of the hydrogel was implemented in ABAQUS by developing a user-defined subroutine UHYPER.

For developing the subroutine, derivatives of with respect to invariants of the deformation measures were calculated and beside the free energy statement were implemented in UHYPER subroutine [22]. First numerical simulation was performed for a homogeneous shell with constant properties and the results were obtained and compared with analytical ones to validate the analytical and numerical methods. The element type was CPE8RH in ABAQUS which is a plane strain one with reduced integration to avoid locking problems. Due to cylindrical symmetry of the shell only a quarter of the shell was considered in FEM. Mesh size of the model was adequately refined to reach convergent solution in each case. As an example, the mesh dependency of the FEM model is depicted in Fig. 2 for displacement of the outer radius of the shell and for 32 layers shell. As depicted in Fig. 2, to reach convergent solution, FEM model with 7680 elements was chosen for numerical solutions.

Then the results were obtained and plotted for multi-layered model and compared with analytical results. As an example, in Fig. 3, the obtained true stress of the FEM model is depicted for $B/A = 2$ in which the zero stress condition for the outer radius and zero displacement condition for the inner radius of the shell is observed which is in agreement with assumptions of the problem. The validity of analytical model was confirmed by the numerical results as discussed in the next section where the results of both methods are presented and more study on the swelling behavior of the shell is provided.

5. Results and Discussion

In this section, first the results are obtained and presented. Then, the performance of the analytical method is checked. First, both methods were employed for studying the swelling behavior of homogeneous shell with $N_0\nu = N_1\nu = 0.01, 0.005$ and the obtained results are illustrated in Fig. 4. As observed in Fig. 4, very good agreement exists between FEM results and analytical ones that confirms the FEM and analytical results validity. On the other hand, the results for swelling behavior of a FGM shell with $N_0\nu = 0.01$ and $N_1\nu = 0.005$ are obtained and also presented in Figure 4 for analytical method. In this figure, normalized true distance is defined as $r(R)/A$. As illustrated in Fig. 4, the obtained results are different for homogeneous and FGM shell as expected. Obviously, the obtained results for outer radius of the FGM shell is different from both homogeneous ones and is between them. Therefore, considering the FGM effects in these structures is important.

The analytical results obtained for FGM hydrogel should be validated. Thus, numerical simulations were carried out for multi-layered shell with linear variation of the hydrogel cross-linking density in radial direction. The results of both analytical and numerical methods for the FGM shell as well as multi-layered one are ob-

![Fig. 2. Displacement of outer radius of the shell for 32-layer shell versus different number of elements of FEM model.](image1)

![Fig. 3. FEM results for 32 layers hydrogel shell at 302 K and for the shell with $B/A = 2.0$.](image2)
tained and shown in Fig. 5 in which radial and tangential true stresses are calculated and plotted in terms of the normalized true distance. As shown in Fig. 5, a jump is observed for tangential stress in FEM results which is due to discontinuity in the properties of adjacent layers. By increasing the number of layers, the mentioned jump in tangential stress is damped and as a result, the FEM curves approach to analytical ones which is expected. Moreover, very good agreement between the numerical simulations with large number of layers and the analytical results is observed that guarantees the analytical solution performance for FGM solutions.

For the different shell thicknesses, the analytical model was solved and the outer radius of the hydrogel shell is obtained and shown in Figs. 6-8 versus to temperature changes. To the better understanding of the FGM effects, two extra homogenous cases for \( N_0 \nu = N_1 \nu = 0.005 \) and \( N_0 \nu = N_1 \nu = 0.001 \) are presented beside the FGM solutions in the same figures.

As can be seen, the outer radius of the shell increases by the temperature decrease in all cases due to swelling of the shell. It can be noted that the value of outer radius of the shell encounters a large change in temperature range of 305-307K which is in the vicinity of the transition temperature of PNIPAM. In temperatures below this range the hydrogel is in swollen state and for the temperatures above this limits the hydrogel is in shrunken state in which the water content of the shell is small. In all figures, the outer radius is larger for the homogeneous case of \( N_0 \nu = N_1 \nu = 0.005 \) which is due to small amount of cross-linking of the hydrogel shell in this case. Moreover, for other homogenous case of \( N_0 \nu = N_1 \nu = 0.001 \), smaller value was obtained for outer radius of the shell because of large cross-linking density of the hydrogel. Furthermore, the outer radius of the FGM hydrogel was always between the two homogeneous solutions as expected. This is because the FGM shell properties is an average of the material properties in inner and outer radii of the shell. Thus, the results were rational and the analytical model shows a good performance for studying the hydrogel shell swelling behavior due to temperature changes.
On the other hand, by increasing the thickness ratio $B/A$, the difference between FGM solution and homogeneous one is larger due to a decrease in the shell stiffness which originates from decreasing the hydrogel cross-linking density in the outer layers of the shell. Additionally, for larger values of the thickness ratio the outer diameter of the shell has larger values which is reasonable due to large initial radius of the outer layer and lower level of the confinement for the thicker shell.

As depicted in above figures, the difference between the FGM solution and homogeneous solution is considerable in all cases which is an important point for design and study of this structure especially for micro-valves application in which the outer radius of the hydrogel determines the closing temperature of the micro-valve. To better understand this point, a micro-valve in a channel can be considered with width of 6A as shown in Fig. 10.

For this case, when the outer diameter of the shell is equal to 3A the shell is in contact with the channel.
wall and the micro-valve is closed. The temperature at which this phenomenon occurs is named closing temperature.

As shown in Fig. 8, the closing temperature for the FGM solution is different from two other homogenous ones by amount of nearly 0.5K. This amount of difference is very important in this devices due to their fine tuning nature. It is worthwhile to mention that by increasing the channel width this difference in closing temperature of the FGM and homogenous shells also increases which distinguishes the FGM importance in the under-study micro-valve. Therefore, it can be concluded that considering the FGM effect in swelling of the FGM hydrogel shell is very important which is not negligible.

6. Conclusions

In this work inhomogeneous swelling behavior of a cylindrical temperature sensitive hydrogel shell was studied due to temperature changes for the FGM shell. The hydrogel shell was assumed to be rested on a rigid core at the inner radius and experience stress-free condition in the outer radius. The swelling behavior of the shell was performed both analytically and numerically. The analytical model validity was confirmed by the numerical results due to very good agreement between the results. Finally, the analytical model was employed to study the effect of the thickness of the shell on its swelling behavior. The obtained results in this work showed the analytical model performance in swelling study of the FGM hydrogel shells with application in smart hydrogel micro-valves. Furthermore, considering the FGM effect in the FGM shells was important and had a considerable effect on the closing temperature of the micro-valve.
